Description

Nowadays, because of the wave of cold, long periods of rain appears in HZNU and leads to the result that there are many little lakes here and there. Now, CCJ is interested in the lakes.

To simplify the problem, we consider the map of HZNU is a rectangle of the size $n \times m$, which consists of cells of size 1×1 . Each cell is either land or water, and lake is a set of water cells. The map is surrounded by water. Two cells are considered adjacent when they share a side (e.g. $[x][y]$ and $[x][y-1]$ are adjacent while $[x][y]$ and $[x-1][y-1]$ are not.) If and only if two cells are adjacent, they can be merged into the same lake. Obviously, **if the water cell in the map is adjacent with the border, it can't be a lake.**

your task is to calculate the number of lakes in the map.

See the sample for more details.

Input

The first line of inputs contain two integers n, m ($3 \leq n, m \leq 100$)-----the size of the map.

Then n lines contain m characters each to describe the map, each character is a '*' (it means this cell is land) or '.' (it means this cell is water).

This problem you don't need to input multiple test cases.

Output

Output the number of lakes in the map.
